# Overview

- ◆ What is overpressure (OP) processing and why use it?
- ◆ OP improves microstructure
- ◆ OP increases  $J_c$
- ◆ Summary

# Density varies through multi-step 2223 process

Full density 6.3 g/cc

Jiang et al. SuST 2001

- ◆ Density decreases as 2223 forms
- ◆ Rolling increases density
- ◆ Core can dedensify in final heat treatment
- ◆ 10-30% porosity exists in best multifilament tapes
- ◆ Cracks caused by IR never completely heal

# What is overpressure (OP) processing?

## Applies isostatic pressure to compress samples

- ◆ OP processing is a variant of hot isostatic pressing (HIP)
- ◆ Mixture of inert gas and  $O_2$
- ◆ Inert gas applies pressure  $<200$  atm
- ◆  $pO_2$  sets thermodynamic condition needed to form 2223  
 $pO_2 = 0.075$  atm

Ultimate Goal: 1 deformation/sinter (1DS) process

# Overview of ORNL static OP system

Easy to change initial  $P_{\text{total}}$  and  $p\text{O}_2$ , but gas is not replaced,  $P_{\text{total}}$  and  $p\text{O}_2$  change during run

# Overview of UW flow OP system

Gas continuously replaced during run;  
 $P_{\text{total}}$  and  $p\text{O}_2$  remain constant

# UW flow OP system, 900°C, 200 atm

← 1.3 m →

University of Wisconsin  
Applied Superconductivity Center

# Where to begin with OP?

$T_{\max}$ ,  $P_{\text{total}}$ , and  $pO_2$  are the most important OP parameters

- Use simple HT schedule to optimize  $T_{\max}$
- Modify J.Jiang's 1 atm processing schedule for OP
- Address  $pO_2$  uncertainty in OP gas mixture  
 $pO_2 = 0.075$  to  $0.10$  atm at 148 atm

# Simple heat treatment to optimize $T_{max}$

$P_{total}=148\text{atm}$ ,  $pO_2=0.077\text{atm}$  (design)

# Microstructure as a function of $T_{max}$ , 148atm

804C

808C

812C

816C

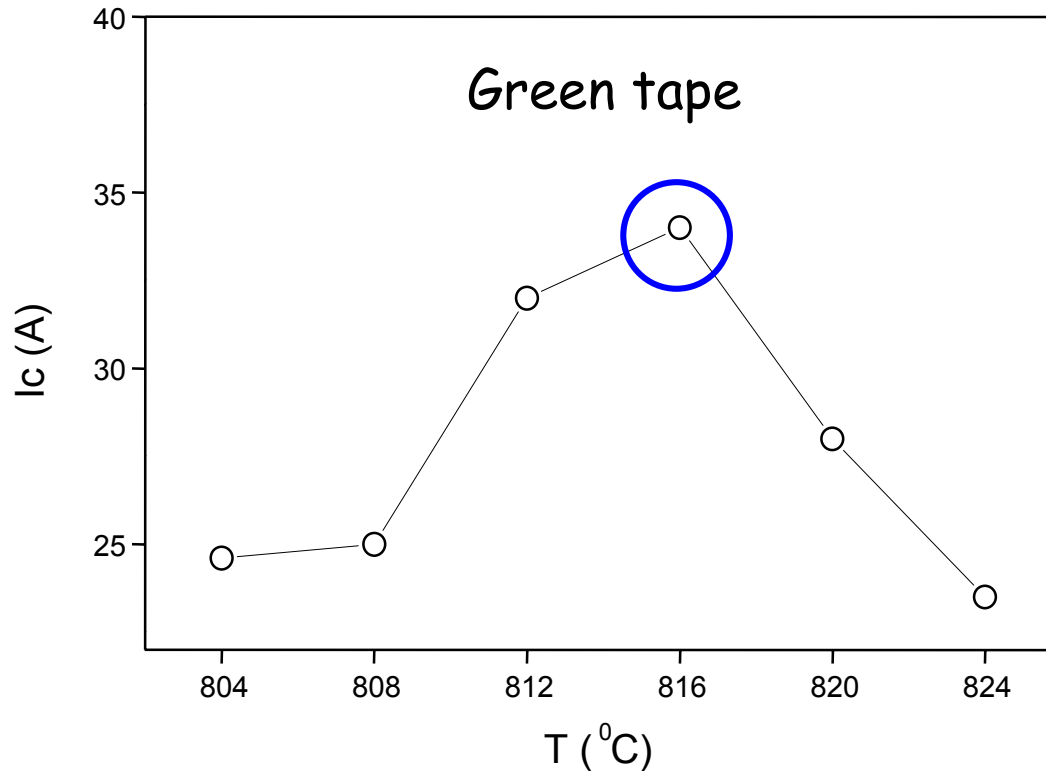

820C

824C

# Ic varies with temperature - OP 148 atm

# OP thermal process

Simplified the 1 atm HT for OP processing

$$P_{\text{total}}=148 \text{ atm}, p\text{O}_2=0.077 \text{ atm (design)}$$

See Jiang - 2MM04  
Tuesday 4:00pm

At  $P_{\text{total}} = 1 \text{ atm}$ ,  $p\text{O}_2$  has small influence on HT1 and IR, some on GT,

# OP improves microstructure

- ◆ Densifies filaments
- ◆ Removes porosity
- ◆ Heals deformation cracks

# OP removes porosity and heals cracks

1atm, multifilamentary IR tape

$$J_c = 33.5 \text{ kA/cm}^2$$

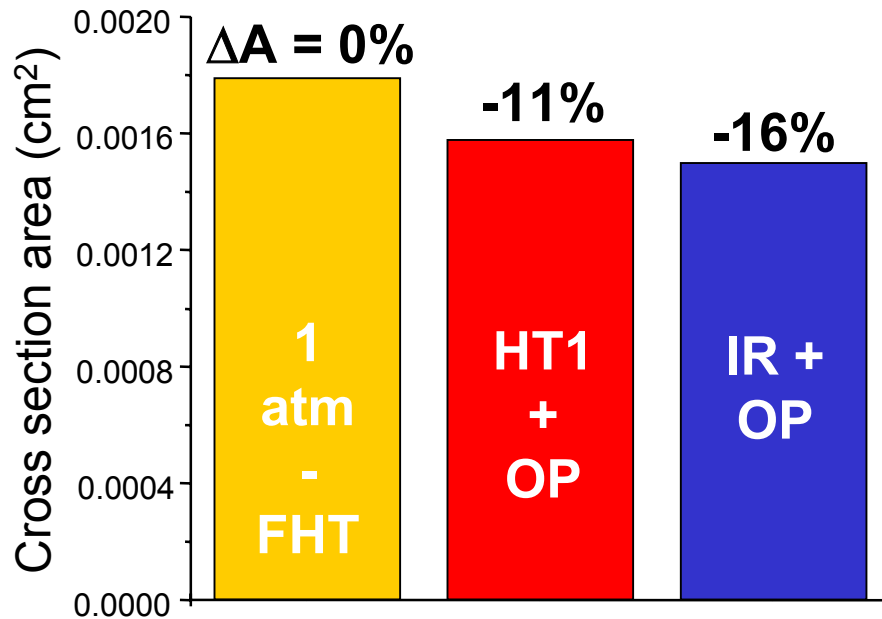

148atm, multifilamentary IR tape

$$J_c = 58.7 \text{ kA/cm}^2$$

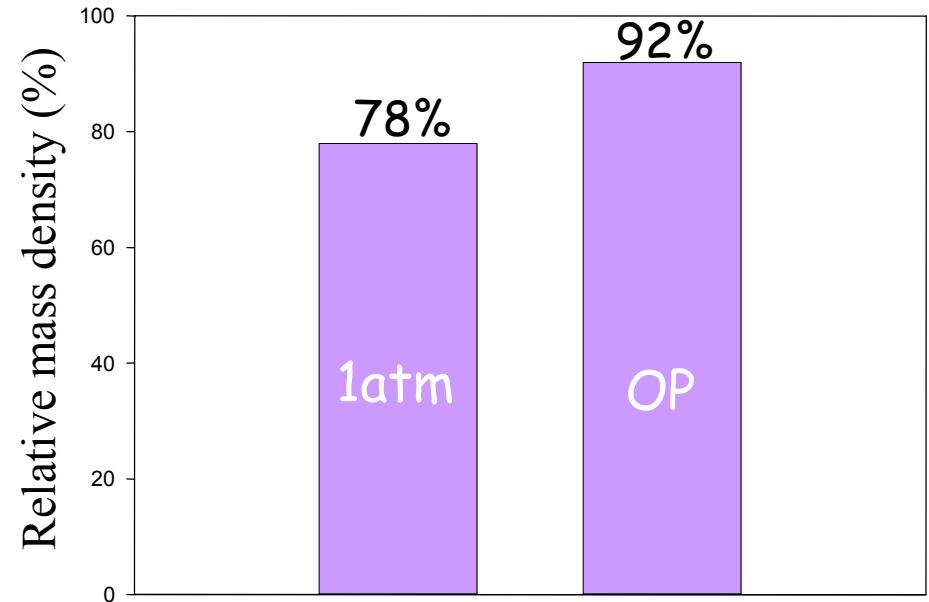

# OP densifies BSCCO filaments

Core cross section area

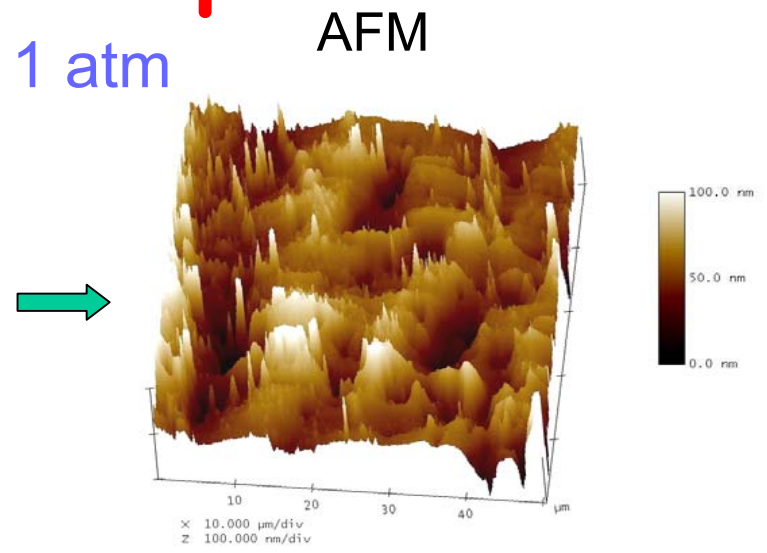

Mass density

# AFM micrographs show lower porosity in OP tape

# OP increases $J_c$

- ◆ OP drives  $J_c$  up by
  - ◆ Densifying core
  - ◆ Reducing  $2212$
  - ◆ Improving connectivity

# OP increases $J_c$

$J_c$ (SF) of multifilamentary samples

Applied Superconductivity Center

# Direct comparison of connectivity

$X = 50 \text{ kA/cm}^2$

Transport  $J_c$ : 1 atm  $39 \text{ kA/cm}^2$ , OP  $48 \text{ kA/cm}^2$

University of Wisconsin  
Applied Superconductivity Center

# What next?

- ◆ Optimize OP processing
- ◆ Combine OP with other novel processes
- ◆ OP processing at low pressure

# Nonsuperconducting 2<sup>nd</sup> phases and microporosity still in OP tape

$J_c = 58.7 \text{ kA/cm}^2$  , 148 atm

# How low can $P_{\text{total}}$ go?

# Summary

- ◆ OP improves Bi2223 microstructure by densifying filaments - remove porosity, heal cracks
- ◆ OP increases  $J_c$  by several mechanisms
  - ◆ OP increase  $J_c$  by ~20-70% wrt 1 atm processing, new record value of 22.4 kA/cm<sup>2</sup> at 77K, 0.1T
  - ◆ OP increases  $J_c$  by densifying core, reducing 2212, improving connectivity
- ◆ OP needs to be optimized - eliminate 2<sup>nd</sup> phases and microporosity
- ◆ OP densifies tape at 65 atm, lower pressure experiments are underway
